1 Biologically Conserved Positions

None of the variants for the biologically conserved positions were called using both variant callers, indicating that the variants were potential false positives (Manuscript Table 2, Tables S4 and S5). Consensus base quality statistics for biologically conserved positions (Table S1).

Table S1: Biologically Conserved Position Base Qualities Characteristics of consensus based calls for conserved bases. Normalized quality values were obtained by dividing raw quality score (Raw Qual) assigned by GATK for each biologically conserved base position by the depth of coverage for that position

A number of false positive variant calls were due to low sequencing coverage because the targeted sequencing strategy was responsible for false positive variant calls in six of the eight "454" datasets, excluding LGC *E. coli* replicate 2 and *L. monocytogenes* replicate 1. For those six datasets, a variant was called at the last position in the gap between the two sequencing regions, bases 940 and 963 relative to reference sequences for *E. coli* and *L. monocytogenes*, respectively. A 40 bp region that was not part of the targeted sequencing region had significantly lower median coverage than the targeted region (2 X vs. 30,110 X, respectively) for all "454" datasets combined (Figures 1 and 2).

A number of false postive variants were called due to contaminants. A low level of containating reads (150) were present in the LGC *L. monocytogenes* rep 1 dataset. A BLAST analysis of a representative of these reads indicated that they were from *E. coli* (E value of 0.0), a well known contaminant of molecular biology reagents (Section 4). A number of Escherichia coli strains E value of 0.0. in LGC Lmono rep 1 454 dataset. False positive variant calls were also attributable to the sequencing strategy and the variant calling algorithm. Resulting in a number of variants called due to strand bias. Stand bias was identified as the cause of the false positive variant call because greater than 99% of the reads were covering the variant bases were in the same direction. The strand bias was a product of the amplicon-based sequencing. For the *E. coli* dataset the variant was at the 3 prime end of the region 1 amplicon (Fig. 1) and the variant in the *L. monocytogenes* was as the 5 prime end of the region 2 amplicon (Fig. 2). As a result a majority of the reads covering the variants were in a single direction as the reads in the other direction were not long enough to cover the variant. For whole genome sequencing data, read direction biases can indicate a systematic error. The UnifiedGenotyper variant caller takes into consideration strand bias resulting in the false positive variant calls and reports strand bias using the Fisher exact test statistic (see Table 2). A filtering step is

commonly performed when calling SNPs that would have identified these as false positive variants due to the low number of reads with the variant base.	

2 Biologically Variable Positions

To determine the ratio of bases at the biologically variant positions, a novel Bayesian analysis based on binomial sampling theory was developed (Supplemental Computational Methods). According to the binomial distribution, the observed base ratios, while precise (due to high coverage), differed significantly from all potential copy ratios. Subsequently given, the observed base ratios, a Bayesian approach was used to identify the most probable copy ratio out of the possible abundant base ratios assuming *E. coli* and *L. monocytogenes* have seven and six 16S gene copies respectively (Figs. S1 and S2).

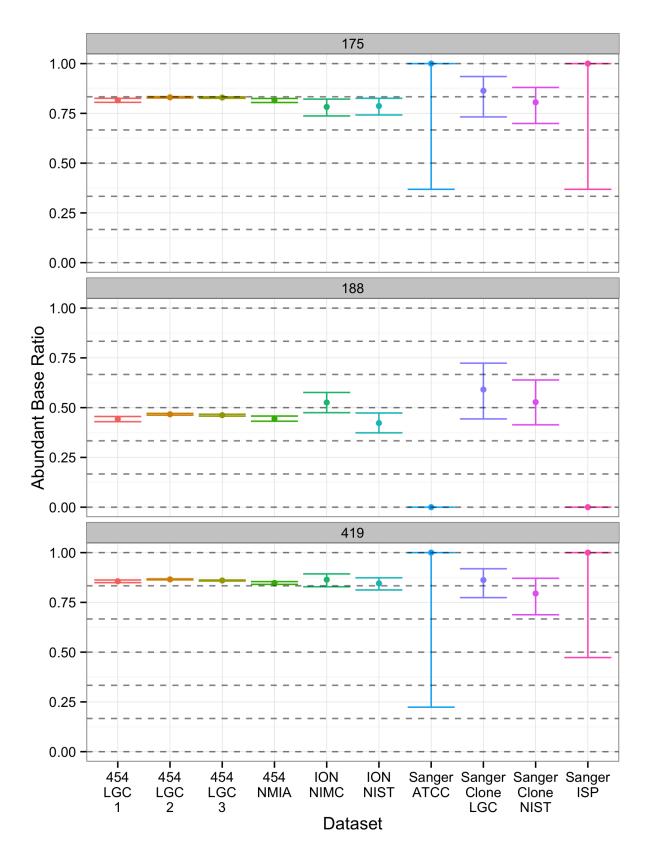

Figure S1: Base ratios at three biologically variable positions (175, 188 and 419) in L. monocytogenes. Variable positions shown in grey box above each graph. Error bars represent the 95 % posterior credibility interval estimated from a beta binomial distribution where is the major base count + 1 and is the minor base count + 1. One sided credibile intervals were calculated for prior probabilities of 0 and 1. Grey dashed lines indicate the potential base ratios assuming six gene copies (i.e. 0:6 corresponds to 0, 2:4 to 0.33, 3:3 to 0.5, 4:2 to 0.66, 5:1 to 0.83 and 6:0 to 1).

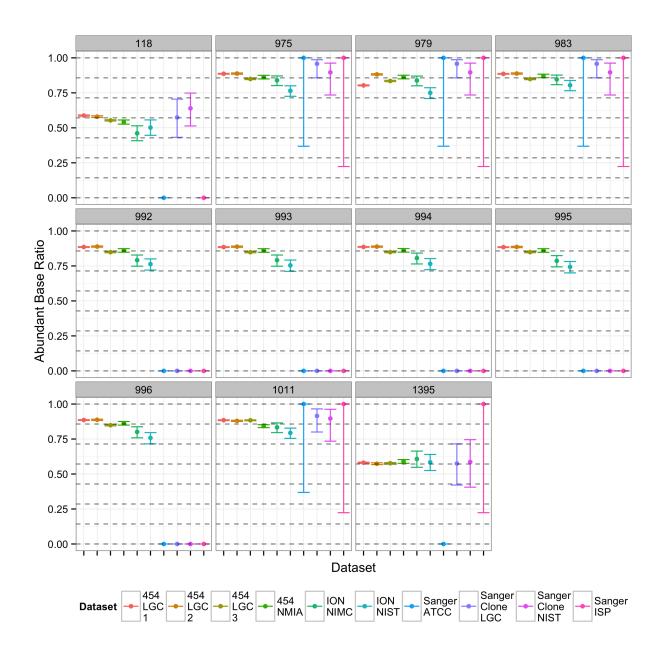

Figure S2: Base ratios at eleven biologically variable positions in $E.\ coli.$ Variable positions shown in grey box above each graph. Error bars represent the 95 % posterior credibility interval estimated from a beta binomial distribution where is the major base count + 1 and is the minor base count + 1. One sided credibile intervals were calculated for prior probabilities of 0 and 1. Grey dashed lines indicate the potential base ratios assuming seven gene copies, (i.e. 0:7 to 0; 1:6 to 0.14; 2:5 to 0.26; 3:4 to 0.43, 4:3 to 0.57; 5:2 to 0.71; 6:1 to 0.86; and 7:0 to 1).

3 Likely sets of variant combinations

Most likely combination of variant strings for "454" and Sanger Clone library datasets (Table S2 and Table S3).

Table S2: Estimated most likely set of variant combinations for *E. coli*. See supplemental compu-

tation methods for how chimera and likelihood were calculated.

4 Appendix

Full List of False Positive Variants

All variants called by the 8 piplines used during the pipeline validation along with the suspected cause of the variant. The following abbreviations were used in Tables S4 and S5: Org - Organism, Plat - sequencing platform, Rep - replicate, Map - read mapping algorithm, Var - variant calling algorithm, POS - base position relative to the reference, DP - coverage, QUAL - confidence in variant call assigned my variant calling algorithm, MQ - mapping quality score assigned by mapping algorithm, FS - fisher strain bias test statistic, Cause - hypothesized cause of false positive variant call. See supplemental manuscript methods section for mapping algorithm and variant calling algorithm descriptions. Note that for the NIST Ion Torrent L. monocytogenes dataset at position 792 a variant was called by the UnifiedGenotyper Variant Calling Algorithm when the reads were mapped using both bwa and tmap, but the FS score was only above 60 when the reads were mapped with tmap. Upon manual inspection of the results we attributed the false positive to a strand bias.

Table S4: *E. coli* Pipeline Comparison Characteristics of variant calls for different bioinformatic pipelines.

Contaminants - BLAST results

BLAST reports for representative sequences of reads responsible for false positive variant calls in the LGC $L.\ monocytogenes\ "454"$ rep 1 dataset.

BLASTN 2.2.29+

ALIGNMENTS

>ref|NC_000913.3| Escherichia coli str. K-12 substr. MG1655, complete genome Length=4641652

Features in this part of subject sequence: rRNA-16S ribosomal RNA of rrnH operon

Score = 979 bits (530), Expect = 0.0
Identities = 539/543 (99%), Gaps = 2/543 (0%)
Strand=Plus/Plus
